## Contents

Preface .....  6
Synopsis .....  8
1 Methods ..... 10
1.1 Data exchange ..... 10
1.2 Hydrography ..... 10
1.3 Pelagic trawl survey for 0-group fish ..... 10
1.3.1 Abundance indices ..... 10
1.3.2 Biomass indices ..... 11
1.4 Acoustic survey for pelagic fish ..... 11
1.5 Bottom trawl survey for demersal fish ..... 12
1.6 Plankton investigations ..... 12
1.7 Fish stomach investigations ..... 14
1.8 Marine mammal and seabird observations ..... 14
1.9 Benthos investigation ..... 15
1.10 Investigations of pollutantspollutants and observation of garbage ..... 15
1.11 Collection of samples for genetic analysis ..... 16
1.12 Recommendations for station sampling ..... 17
2 Results and discussion ..... 17
2.1 Hydrographical conditions ..... 17
2.1.1 Standard sections ..... 17
2.1.2 Horizontal distribution of water masses. ..... 18
2.2 Distribution and abundance of 0-group fish ..... 19
2.2.1 Capelin (Mallotus villosus) ..... 19
2.2.2 Cod (Gadus morhua) ..... 20
2.2.3 Haddock (Melanogrammus aeglefinus) ..... 20
2.2.4 Herring (Clupea harengus) ..... 21
2.2.5 Polar cod (Boreogadus saida) ..... 21
2.2.6 Saithe (Pollachius virens) ..... 22
2.2.7 Redfishes (Sebastes sp.) ..... 22
2.2.8 Greenland halibut (Reinhardtius hippoglossoides) ..... 22
2.2.9 Long rough dab (Hippoglossoides platessoides) ..... 23
2.2.10 Wolffishes (Anarhichas sp.) ..... 23
2.2.11 Sandeel (Ammodytes sp.) ..... 23
2.2.12 Gonatus fabricii ..... 23
2.3 Distribution and abundance of pelagic fish ..... 24
2.3.1 Capelin (Mallotus villosus) ..... 24
2.3.2 Polar cod (Boreogadus saida) ..... 26
2.3.3 Herring (Clupea harengus) ..... 27
2.3.4 Blue whiting (Micromesistius poutassou) ..... 28
2.4 Distribution and abundance of demersal fish ..... 28
2.4.1 Cod (Gadus morhua) ..... 28
2.4.2 Haddock (Melanogrammus aeglefinus) ..... 29
2.4.3 Saithe (Pollachius virens) ..... 29
2.4.4 Greenland halibut (Reinhardtius hippoglossoides) ..... 29
2.4.5 Golden redfish (Sebastes norvegicus) ..... 29
2.4.6 Deep-water redfish (Sebastes mentella) ..... 29
2.4.7 Norway redfish (Sebastes viviparus) ..... 30
2.4.8 Long rough dab (Hippoglossoides platessoides) ..... 30
2.4.9 Wolffishes (Anarhichas spp) ..... 30
2.4.10 Plaice (Pleuronectes platessa) ..... 30
2.4.11 Norway pout (Trisopterus esmarkii) ..... 30
2.4.12 Non target fish species ..... 31
2.5 Ecological interactions ..... 31
2.5.1 The effect of bottom temperature and depth on the distribution of cod and haddock and their biological parameters within these ranges ..... 31
2.6 Phyto- and zooplankton ..... 32
2.7 Marine mammals and seabirds ..... 34
2.7.1 Marine mammals ..... 34
2.8 Seabirds ..... 35
2.9 Benthos ..... 35
2.9.1 Invertebrate benthos ..... 35
2.9.2 Red King crab (Paralithodes camtschaticus) ..... 36
2.9.3 Snow crab (Chionoecetes opilio) ..... 36
2.9.4 Northern shrimp (Pandalus borealis) ..... 36
2.10 Pollution ..... 36
2.10.1 The sunken submarine "Komsomolets". ..... 36

## Preface

The 8th joint survey was carried out during the period 10 August to 5 October 2011. The survey plans and tasks were agreed upon at the annual IMR-PINRO Meeting in March 2011 and all joint work was executed according to this plan.

In 2011, a nearly total coverage of the Barents Sea was obtained, apart from small areas south and north of the "Loophole", where the jurisdiction changed in July 2011 in accordance with the new Norwegian-Russian division line. As there were doubts about exactly where the Russian and Norwegian vessels could operate non of the vessels could enter these areas.

The weather conditions were favourable during most of the survey. "Helmer Hanssen" (9$24 / 8)$ covered the Spitsbergen/Svalbard area, while "Vilnyus" (10/08-3/10) first covered the southeastern part of the Barents Sea and then continued to cover the REEZ from south to north. "Christina E" (25/08-18/09) covered the central parts of the NEEZ and "Johan Hjort" (31/8-05/10) covered the southwestern and western part. From the 18 September and to the end of the survey at the 05 October, only "J.Hjort" and "Vilnyus" took part in the survey, and covered the northern areas east of Spitsbergen/Svalbard.

The demersal fish and benthos investigations were more comprehensive compared to the previous years and were on level of 2009, and there was a small reduction in the oceanographic sampling on the standard sections. The other investigations were kept at the same level as in previous year. Consequently, a joint, but somewhat reduced, ecosystem survey was carried out by IMR and PINRO also in 2011.

The contents of this report cover many but not all aspects of the survey. The content will be updated and available in electronic form in the Internet (www.imr.no).

This report was prepared at a joint meeting in Murmansk, Russia 10-13 October, followed by inputs during November and December 2011. The following specialist and experts participated, either in person or by correspondence:

| Alexander Trofimov | Oceanography |
| :--- | :--- |
| Anatoliy Chetyrkin | Capelin stock prognosis |
| Bente Røttingen | Pelagic fish stocks estimation, preparation of data. |
| Bjarte Bogstad | Capelin stock analyses and prognosis (AFWG chairman) |
| Dmitry Prozorkevich | 0-group, pelagic fish (survey and meeting coordinator) |
| Elena Eriksen | 0 -group fish |
| Ekaterina Murashko | Sampling information, pollution |
| Gjert E. Dingsør | Demersal fish data analyses |
| Harald Gjøsæter | Pelagic fish analyses, methods and descriptions (main editor) |
| Hilde Elise Heldal | Pollution |
| Jamie Alvarez | Pelagic fish stock estimation, data analyses |

| Konstantin Drevetnyak | Demersal fish data analyses |
| :--- | :--- |
| Lis Lindal Jørgensen | Benthos (survey coordinator, responsible editor) |
| Mette Mauritsen | Sea mammals |
| Nikolay Lukin | Sea mammals |
| Nikolay Ushakov | Completing and editing report |
| Padmini Dalpadado | Zooplankton |
| Pavel Lubin | Benthos |
| Pavel Murashko | Demersal fish data analyses |
| Randi Ingvaldsen | Oceanography |
| Sigurd Tjelmeland | Capelin stock analyses and prognosis |
| Tatyana Prokhorova | Sampling information, data fitness checking, pollution |
| Tor Knutsen | Zooplankton |
| Torild Johansen | Genetic |
| Yuri Kovalev | Capelin stock analyses and prognosis |

A list of the participating vessels with their respective scientific crews is given in Appendix I.

## Synopsis

The main aim of the ecosystem survey was to collect data about distribution and abundance of all sea organisms, including phytoplankton, zooplankton, pelagic and demersal fish species, benthos, seabirds and mammals. An important task was also to collect information about sea environment, pollution and several fish-parameters (age, stomach content, etc).

The water temperatures below 50 m depth were higher $\left(0.2-0.7^{\circ} \mathrm{C}\right)$ than the long-term mean and similar to what was observed in 2010. At the surface, the temperatures were much higher than both the long-term mean and the previous year.

The zooplankton biomass (western part of the Barents Sea) was close to the long-term mean in 2011. There is evidence of distinctly higher biomass south of Spitsbergen/Svalbard and between the Bear island and Norwegian mainland. In the eastern Barents Sea the highest biomass were observed in the central part of the sea (northern areas not covered).

The invertebrate benthic biomass distribution was generally the same as in previous years. Echinoderms make up the largest proportion in the central and northern part of the Sea, the crustaceans in the central and eastern parts, the cnidarians in the north-eastern, and sponges in the south-western and north-eastern Barents Sea and along the western and northern coasts of Spitsbergen/Svalbard.

The king crab was distributed between 28 and $45^{\circ} \mathrm{E}$ with max. 6 individuals per nmi. The area and number of king crab has slightly increased.

An eastern distribution of the snow crab was, as previous years, recorded with abundances up to 2400 individuals per nmi. This is an increase from 2010 when it was recorded with 8-10 individuals per trawl.

Northern shrimp is widely distributed in the Barents Sea with $0-164 \mathrm{~kg} / \mathrm{nmi}$. The average catch was lower than in previous years, but the densest concentrations were found around Spitsbergen/Svalbard and in the central parts of the Barents Sea.

The 2011 year-classes (0-group) of cod, capelin and haddock were rich. Herring, redfish, saithe and long rough dab were estimated as poor. The 0 -group year-class of polar cod is slightly above average and Greenland halibut is somewhat below the long term mean level.

The total capelin stock was estimated at 3.71 million tonnes, which is $6 \%$ higher than last year. About 2.1 million tonnes were assumed to be maturing. Estimated maturing stock is 3\% above the last year's estimate and higher than the long term mean level. The polar cod stock was estimated to be 0.86 million tonnes, that is $40 \%$ less than in 2010 but somewhat above the long term mean level. The number of juvenile Norwegian spring spawning herring in the Barents Sea has slightly decreased compared to last year and was estimated to be 1.6 billion individuals. Spring spawning herring was not found in the south-eastern part. Blue whiting of
age groups 1 to 9 , but mostly age $5-7$, were observed in the western part of the surveyed area. The biomass of this stock, estimated to be 0.13 million tonnes, is still decreasing compared to 2010.

Cod were distributed far to the north. The abundance index for age groups 1 year and older was at the same level as in 2009 and 2010. Haddock had a distribution similar to in 2010.

The white-beaked dolphin is the most frequent toothed whale and mainly found along the polar front. Minke and humpback whales were the most frequently baleen whales found, and were mainly located on shallow banks north of the polar front. Few harp seals were observed in the northern area.

Investigations from the area adjacent to the sunken nuclear submarine "Komsomolets" do not indicate significant leakages.

## 1 Methods

### 1.1 Data exchange

Data on cruise tracks, hydrography, trawl catches, integrator values etc. were exchanged by email between all vessels during the survey. All the Russian survey data were transmitted to "J. Hjort", while the Norwegian hydrographic data were transmitted to "Vilnyus". The final survey data from all vessels were collected during the meeting after the survey, which was arranged in Murmansk on 10-13 October 2011.

### 1.2 Hydrography

The oceanographic investigations consisted of measurements of temperature and salinity in depth profiles distributed over the total investigated area and along the sections Fugløya-Bear Island, Vardø-North, Kola, and Kanin (fig 2.2). All vessels used CTD-probes.

### 1.3 Pelagic trawl survey for 0-group fish

Since 1965 surveys, in August/September, have provided annual information on the abundance and spatial distribution of pelagically distributed 0 -group fish of Barents Sea. These species include capelin (Mallotus villosus), Norwegian spring spawning herring (Clupea harengus), Northeast Arctic cod (Gadus morhua) and haddock (Melanogrammus aeglefinus) as well as polar cod (Boreogadus saida), long rough dab (Hippoglossus platessoides), Greenland halibut (Reinhardtius hippoglossus), redfish (Sebastes spp.) and several others.

The estimated distribution and abundance of 0-group fish were based on the pelagic trawl catches, measuring the number of individuals per square nautical mile. Trawl hauls were made with a mid-water trawl, with a quadratic mouth opening of 20x20 m. Since 1980 a standard procedure has been used on all vessels. This trawling procedure consists of tows covering 3 depths, each over a distance of 0.5 nautical miles. The headline of the trawl is located at 0,20 and 40 m and with trawling speed of 3 knots. Additional tows at 60,80 and 100 m , also of 0.5 nm , were made when the echo-sounder recorded 0 -group fish layer deeper than 40 m depth.

### 1.3.1 Abundance indices

The history of development of 0-group investigation, assessment methods and recalculation of abundance indices is described in details in earlier versions of the survey report (Anon. 1980, Anon. 2004) and in Eriksen et al., 2009.

In 2011 the abundance indices (with and without correction for capture efficiency) was recalculated for the period 2004-2010 due to mistakes of input data in to the calculation program. Recalculation of abundance indices led to some changing, but of very small degree.

### 1.3.2 Biomass indices

The 0 -group fish biomass was calculated for the period 1993-2009 by Eriksen et al. (2011), and the computation of biomass indices is made using the stratified sample mean method of swept area estimates (Dingsør 2005). The capture efficiency of the sampling trawl differ between species and decreases with decreasing 0-group length (Godø et al. 1993; Hylen et al. 1995). The capture correction factor for cod, haddock and herring biomass was found by calculating the ratio between abundance indices (with and without capture efficiency). For capelin, which is small and not herded to any extent by the net walls, we chose to calculate the biomass according to the effective wingspread of the trawl.

### 1.4 Acoustic survey for pelagic fish

All regions of the Barents Sea and adjacent areas of the Norwegian Sea were covered by an acoustic survey, with course lines about 35 nautical miles apart.

All participating vessels used ER-60 echo sounders (with ER-60 software). "Christina E", "J. Hjort" and "Helmer Hanssen" used LSSS ("Large scale survey system"), while "Vilnyus" used FAMAS for postprocessing of acoustic data. "J. Hjort" and "Helmer Hanssen" were equipped with transducers on adjustable keels that can be lowered in rough weather to avoid the damping effect of bubbles. Echo intensities per nautical mile were integrated continuously, and mean values per 1 nautical mile were recorded for mapping and further calculations. The echograms, with their corresponding $\mathrm{s}_{\mathrm{A}}$-values, were scrutinized every day. Contributions from the seabed, false echoes, and noise were deleted.

The corrected values for integrated echo intensity were allocated to species according to the trace patterns and the frequency responses of the echograms and the composition of the trawl catches. For pelagic species, data from pelagic trawl hauls and bottom trawl hauls considered representative for the pelagic component of the stocks, which is measured acoustically, were included in the stock abundance calculations. For demersal species, mostly bottom trawl stations were used.

The echo sounders were watched continuously, and trawl hauls in addition to the predetermined hauls were carried out whenever the recordings changed their characteristics and/or the need for biological data made it necessary. Trawling was thus carried out both for identification purposes and to obtain biological observations, i.e., length, weight, maturity stage, stomach data, and age.

The vessels gave the $\mathrm{s}_{\mathrm{A}}$-values in absolute terms based on sphere calibrations, that is, as scattering cross section in $\mathrm{m}^{2}$ per square nautical mile. The acoustic equipment of the vessels was calibrated by standard spheres.

The computations of number of individuals and biomass per length-and age group of the pelagic fish stocks were done in the same way as in previous years. For details see the 2006 ecosystem survey report (Anon. 2006).

Acoustic registrations of demersal fish were carried out along all cruise tracks, with division of $\mathrm{s}_{\mathrm{A}}$-values by species based on trawl catches data. Acoustic stock size estimates have, however, not been calculated for these species.

### 1.5 Bottom trawl survey for demersal fish

More bottom trawl stations were made by the Norwegian vessels in 2011 compared with 2010. The number and biomass of demersal fish calculated from bottom trawl catches using the "swept-area" method (Jacobsen et al 1997, Dickson 1993a, Dickson 1993b). In this report, preliminary calculations of numbers and biomass are shown for the total stocks.

A new strata system was constructed in 2004 (IMR) and 2009 (PINRO) covering the whole Barents Sea to include the total survey area. The new geographic system is also depth stratified using GEBCO depth data.

### 1.6 Plankton investigations

Data on phytoplankton abundance was obtained in several ways during the joint RussianNorwegian Survey. On the Norwegian vessels "RV Johan Hjort" and "Helmer Hansen" samples for chlorophyll $\boldsymbol{a}$ were obtained at nearly all CTD stations through filtration of water from water bottles at discrete depths from $0-100 \mathrm{~m}$ including a surface sample taken using a bucket. On the Norwegian vessel "Christina E", no CTD with rosette sampler was available and the chlorophyll $\boldsymbol{a}$ and nutrient samples were collected with standard closable water bottles attached to a wire for predetermined depth sampling. A total of 11 water bottles were used simultaneously, slightly depending on maximum bottom depth. The total number of samples varied slightly depending on bottom depth at the specific localities. Sea water samples were filtered using GFC filters, and samples were frozen for later analysis of chl $\boldsymbol{a}$ content at the IMR laboratory. For the vessels mentioned above nutrient samples were obtained from the same water bottles on most CTD stations, at depths from the surface to the bottom according to a predefined scheme as determined for the Ecosystem cruise and specific bottom depth of each station. Normally, onboard "G.O. Sars" a fluorimeter is used as an additional instrument, connected to the CTD, logging chl $\boldsymbol{a}$ fluorescence as a continuous vertical profile along with temperature and salinity for all CTD stations. These data must be calibrated with the help of chl $\boldsymbol{a}$ determined from the water bottle samples obtained at the same stations. However, in 2011 no such measurements were undertaken from the Norwegian vessels.

Samples for phytoplankton species composition and abundance have been obtained from the Norwegian vessels "Christina E", "RV Johan Hjort" and "Helmer Hansen". For every second or third station quantitative water samples were obtained from water bottles at 5, 10, 20 and

30 m depth. Immediate upon retrieval of the seawater rosette sampler, one 25 ml phytoplankton sample were taken from each bottle at the above mentioned depths. The samples were pooled in a dark light-protected 100 ml flask adding 2 ml lugol as fixative for later analysis. Slightly less frequent a $10 \mu \mathrm{~m}$ meshed phytoplankton net with a $0.1 \mathrm{~m}^{2}$ opening was vertically operated from $0-30 \mathrm{~m}$ to obtain qualitative phytoplankton samples. After gentle mixing of the water from the net cod-end, one dark light-protected 100 ml flasks was filled with approximately 80 ml seawater, then adding $2.5 \mathrm{ml} \mathrm{20} \mathrm{\%}$ formalin for fixation. At some stations a parallel sample was taken and fixated in 2 ml lugol.

On Russian vessels species composition, diversity, size structure, abundance/biomass and vertical and spatial distribution of microalgae were studied. Phytoplankton samples were obtained at the oceanographic stations using seawater rosette sampler from three depths or depth layers: the surface, a layer of 5 meters above the pycnocline, and the bottom layer (only on "Vilnyus"). Samples were preserved with buffered $40 \%$ formalin to a final concentration of $2-4 \%$ immediately after sampling.

Zooplankton sampling on all three Norwegian vessels was carried out by WP-2 plankton nets with a $0.25 \mathrm{~m}^{2}$ opening and $180 \mu \mathrm{~m}$ mesh size. On "Helmer Hansen" samples were collected from 200-0m, while on the other vessel "RV Johan Hjort" and "Christina E", samples were obtained from bottom- 0 m , omitting the $100-0 \mathrm{~m}$ haul in 2010. In addition, stratified sampling was conducted with the MOCNESS multinet plankton sampler on board "RV Johan Hjort". The sampling on the Russian vessel was carried out by Juday-nets with $0.1-\mathrm{m}^{2}$ opening and $180 \mu \mathrm{~m}$ mesh size. Depth intervals for plankton sampling were the bottom- $0-\mathrm{m}, 100-0-\mathrm{m}$ and 50-0-m layers.

In addition, sampling of macroplankton were taken by plankton net BR (with a $0.2 \mathrm{~m}^{2}$ opening and $564 \mu \mathrm{~m}$ mesh size) connected with bottom trawl on the Russian vessel "Vilnyus", and with a new macroplankton trawl on the Norwegian vessels "Christina E" and "RV Johan Hjort" as described in the Ecosystem manual.

On the Russian vessel "Vilnyus", sampling of macroplankton were taken by plankton net BR (with a $0.2 \mathrm{~m}^{2}$ opening and $564 \mu \mathrm{~m}$ mesh size) connected with bottom trawl.

On board the Norwegian vessels samples were normally split in two, one part was fixated in $4 \%$ borax neutralized formalin for species analysis and the other one was size-fractioned as follows; $>2000 \mu \mathrm{~m}, 2000-1000 \mu \mathrm{~m}$ and $1000-180 \mu \mathrm{~m}$ size categories. These size-fractionated samples were weighed after drying at $60^{\circ} \mathrm{C}$ for 24 hours. For large organisms like medusae and ctenophores their volume fraction were determined by displacement volume onboard the vessels. From the $>2000 \mu \mathrm{~m}$ size fraction krill, shrimps, amphipods, fish and fish larvae were counted and their lengths measured separately before drying. Chaetognaths, Pareuchaeta sp. and Calanus hyperboreus from the $>2000 \mu \mathrm{~m}$ size fraction were counted and dried separately, but their sizes were not measured. All weights were determined at the IMR laboratory when the dry weight samples were returned to Bergen.

Processing of Juday net samples from the Russian vessels included weighing of wet samples to within $0,0001 \mathrm{~g}$, with removal of excessive moisture by a filtering paper for species identification and abundance determination. A more detailed processing of species and stage composition as well as numerical abundance will be undertaken in the laboratory according to standard procedures. Dry weights will be derived using a conversion factor of 0.2. All zooplankton data will be presented as biomass or numbers per $1 \mathrm{~m}^{2}$ surface. As most of the samples are worked up after the survey, the final results will be presented at a later stage.

### 1.7 Fish stomach investigations

According to agreement at the Russian-Norwegian meeting in March 2006, capelin and polar cod stomachs were collected at the Norwegian ("Christina E", "J. Hjort" and "Helmer Hanssen") and Russian ("Vilnyus") vessels in August-October 2011. Also stomach samples of cod were taken according to standard protocol on Norwegian vessels.

On board "Vilnyus", the stomach samples were taken both from commercial (cod, haddock, saithe, capelin, polar cod) and non-commercial (thorny skate) fish species, and 645 stomachs were taken. A total of 101 stomachs were taken from 0 -group cod, haddock and saithe. At the same time 3752 stomachs was taken from 23 fish species and a "short analyse" was carried on the stomachs out at sea during the survey.

The capelin and polar cod stomachs from 2010 are in the final phase of analyses. At IMR 330 and 180 stomachs of capelin and polar cod has been analysed respectively. These data are exchanged with PINRO. The aim is to establish a "stomach database" similar to the one existing for demersal fish.

### 1.8 Marine mammal and seabird observations

Marine mammals observations (species and numbers observed) were recorded onboard the Norwegian research vessels "Christina E.", "Johan Hjort" and the Russian research vessel "Vilnyus". Seabirds were observed from the same vessels, but also included "Helmer Hanssen".

Onboard the Norwegian vessels visual observations were made by three observers from the vessel bridges; one dedicated sea bird observer and two dedicated marine mammal observers. As no marine mammal observers participated on the "Helmer Hansen", the observations recorded from this vessel were obtained from the seabird observer and a master student.

The marine mammal observers covered approximately the front $90^{\circ}$ sector ( $45^{\circ}$ each) and the sea bird observer covering one $90^{\circ}$ sector 300 m wide along the ship side. While most species were recorded continuously along the cruise transects when steaming between stations, the ship-following seabird species (northern fulmars and gulls) were counted every hour.

Onboard the Russian research vessel observations of marine mammals and sea birds were carried out by one observer covering a $45^{\circ}$ sector from roof of the bridge about $9-10 \mathrm{~m}$ above the sea surface level. The observer was recording only along transects between stations, and the ship-following seabird species (northern fulmars and gulls) were counted every hour.

Both observer activity and observer conditions (Beaufort Sea State, visibility and weather) were recorded continuously. Observer activity was limited by weather conditions. When the weather conditions were not sufficiently good for observations observation effort was stopped.

### 1.9 Benthos investigation

The purpose of the benthos investigation is to monitor benthic habitats and communities in the Barents Sea by analysing the bycatch of the Campelen trawl on all Norwegian and Russian vessels. This should lead to criteria for selection of suitable monitoring locations in the Norwegian and Russian EEZ and improved procedures for providing results on benthos relevant for an ecosystem approach to management of marine resources in the Barents Sea.

All invertebrates from the bottom trawl hauls of the Russian RV "Vilnyus" and the Norwegian RV "Christina E", "Johan Hjort", "Helmer Hanssen" was processed to species level in 2011. All individuals was counted and weighed per species. The measures of the invertebrate-group (see survey manual, Jørgensen (2006), was recorded in Reg-Fisk, while the identification down to species was recorded in the IMR-PINRO benthos-database.

### 1.10 Investigations of pollutantspollutants and observation of garbage

Every third year (last time in 2009), IMR carries out thorough investigations of the levels of pollutantspollutants in sea water, sediments and marine biota in the Barents Sea. The analysis includes different hydrocarbons, persistent organic pollutants (POPs) (PCB, DDT, HCH, HCB ) and radionuclides. Monitoring of radionuclides is performed within the monitoring programme "Radioactivity in the Marine Environment" (RAME), which is coordinated by the Norwegian Radiation Protection Authority (NRPA). Monitoring of organic pollutants is performed in close cooperation with NGU (The Geological Survey of Norway) and National Institute of Nutrition and Seafood Research (NIFES). In addition, IMR investigate once a year the levels of radioactive contamination in the vicinity of the Russian nuclear submarine "Komsomolets", which sank in 1989 in international waters in the Norwegian Sea 180-190 km south-southwest of Bear Island at $73^{\circ} 43^{\prime} 16^{\prime \prime} \mathrm{N}$ and $13^{\circ} 16^{\prime} 52^{\prime \prime} \mathrm{E}$ (e.g. Høibråten et al., 1997.

In 2011, IMR's monitoring of pollutants in the Barents Sea was restricted to the sampling from "Komsomolets". At CTD station 626, samples of surface water (approximately 500 L ) were collected from the seawater intake on F/F Johan Hjort and bottom seawater (approximately 500 L ) was collected with a CTD-rosette multi bottle sampler with large (10
L) water samplers. Sediment samples were collected with a sediment sampler of the type "Smøgen Boxcorer". The samples will be analysed for a range of radionuclides (e.g. plutonium-238, plutonium-239,240, cesium-137 and strontium-90).

Onboard "Vilnyus" were taken 10 complex sampling from different parts of REEZ include water, bottom sediments and biota for analyses the PCB, DDT, $\mathrm{HCH}, \mathrm{HCB}$ and radionuclides. During the survey the amount and types of man-made garbage in the survey area were observed. During analysis of trawl catches all types of pollutant (according to the OSPAR Commission (Protection of the marine Environment of the North-East Atlantic Commission) codes were registered and weighted.

The marine mammals observers on the two research vessels («Cristina E» and «Vilnyus») registered the presence of floating man-made garbage on the sea surface. Type of pollutant (according to the OSPAR Commission codes) and approximate volume or size were indicated and noted.

After all types of pollutant were combined into the 8 groups (metal, plastic, glass, paper, oil, wood, rubber, textile) to build maps.

### 1.11 Collection of samples for genetic analysis

Genetic sampling of cod. As part of a large Norwegian sampling program (project "Bestandskomplekser") gill samples were collected from juvenile cod from the total Barents Sea onboard the three Norwegian vessels "Christina E", "Helmer Hanssen" and "Johan Hjort". The plan was to collect samples along transects going east-west and north-south (in total 600 juveniles) to identify possible sub-structures within the Northeast arctic cod stock and to identify possible coastal cod recruitment in the Barents Sea. It was also collected adult cod from the Spitsbergen/Svalbard region onboard "Helmer Hanssen". Samples of adult cod were collected from all cod where also biological information and otoliths were samples.

Genetic samples from shrimps (Pandalus borealis). As part of an ongoing project funded by the Norwegian Research Council to study stock structure of P. borealis in the North Atlantic we collected shrimps from the northwest and south west of Spitsbergen/Svalbard. Only females were collected for this population genetic study. In addition to the genetic sample (muscle tissue from tail region conserved in ethanol), Carapax length was measured from the female shrimps. In addition some shrimp was frozen whole for the same study.

Genetic samples from Sebastes sp. On behalf of Spanish colleagues we collected genetic samples (Gills in ethanol) from the two species of Genus Sebastes: S. mentella and $S$. marinus. These data will be used to study species structure in this genus.

RNA samples from cod species. On behalf of the University of Bergen (UIB) we collected samples on RNA-later. Small liver samples were cut fresh from the fish immediately after
catch and stored in RNA-later in the fridge for one day (to conserve the tissue) and then transferred to freezer for storage until the samples reached Bergen. The purpose of the project is to extract RNA from samples to study gene expression in relation to genes expressed in polluted fish. The study organisms are cod, haddock and capelin. (For further details contact the project manager professor Anders Goksøyr at Bio, UIB.)

### 1.12 Recommendations for station sampling

- The surveys design should not have neighbouring surveys tracks, which are separated in time with more than 1week.
- One should avoid cutting two or more neighbouring stations if lack of time forces some stations to be taken out.
- 0-group investigation: Trawling procedures must be followed, which is based on trawling a distance of $\mathbf{0 . 5}$ nautical miles for each depth (Anon 1980 and Anon 2004). Duration at each depths should not be decided by elapsed time, since the vessels speed may vary during trawling.

## 2 Results and discussion

Altogether, 127 vessel-days were spent at the joint survey in 2011. A comparison with previous years is shown in the text table below. In 2011, the vessels observed about 500000 square nautical miles, and carried out 775 trawl hauls and 487 CTD stations.

| Year | No of vessel days | No of trawl hauls | No of CTD |
| :---: | :---: | :---: | :---: |
| $\mathbf{2 0 0 4}$ | 215 | 1123 | 1144 |
| $\mathbf{2 0 0 5}$ | 208 | 1008 | 1028 |
| $\mathbf{2 0 0 6}$ | 205 | 999 | 1052 |
| $\mathbf{2 0 0 7}$ | 210 | 1007 | 610 |
| $\mathbf{2 0 0 8}$ | 141 | 776 | 776 |
| $\mathbf{2 0 0 9}$ | 127 | 754 | 428 |
| $\mathbf{2 0 1 0}$ | 134 | 710 | 462 |
| $\mathbf{2 0 1 1}$ | 127 | 775 | 486 |

Survey routes with trawl stations; hydrographical stations, and plankton and environmental stations are shown in Figure 2.1, 2.2 and 2.3, respectively.

### 2.1 Hydrographical conditions

### 2.1.1 Standard sections

Figure 2.1.1 shows the temperature and salinity conditions along the oceanographic sections: Fugløya - Bear Island, Vardø-North, Kola, and Kanin. The mean temperatures in the main parts of these sections are presented in Table 2.1.1, along with historical data back to 1965.

Anomalies have been calculated using the long-term means for the periods 1954-1990 (Kanin section) and 1951-2000 (Kola section).

The Fugløya-Bear Island section covers the Atlantic inflow from the Norwegian Sea to the Barents Sea. The southern part of the Vardø-North section covers the Norwegian Coastal Current and the Murman Current containing both coastal and Atlantic water masses, while the northern part covers the Central and Northern Branches of the North Cape Current that carries Atlantic Water. The mean temperature in the $50-200 \mathrm{~m}$ in the Fugløya-Bear Island sections was $0.6^{\circ} \mathrm{C}$ higher than the long-term mean for the period $1965-2011$ and $0.2^{\circ} \mathrm{C}$ higher than in 2010. The mean temperature in the $50-200 \mathrm{~m}$ in the Central Branch of the North Cape Current was about $0.8^{\circ} \mathrm{C}$ above the long-term mean for the period 1965-2011.

The Kola and Kanin sections cover the flow of Coastal and Atlantic waters in the southern Barents Sea. At the middle of August 2011, the mean temperature in the $0-200 \mathrm{~m}$ in the inner and central parts of the Kola Section was $0.3{ }^{\circ} \mathrm{C}$ higher than usual, and it was $0.5-0.6{ }^{\circ} \mathrm{C}$ lower than in 2010. The upper 50 m layer had higher positive anomalies $\left(0.4-0.5^{\circ} \mathrm{C}\right)$ than the deeper layer of $50-200 \mathrm{~m}\left(0.1-0.2^{\circ} \mathrm{C}\right)$. In the outer part of the section, the anomalies in the layers of $0-50,0-200$ and $50-200 \mathrm{~m}$ were $0.7^{\circ} \mathrm{C}$ like in 2010. Towards the end of September, the positive temperature anomalies in the upper 50 m layer of the Kola section increased significantly (about three times), while they remained almost unchanged in the $50-200 \mathrm{~m}$ layer. The increase was probably due to more intensive warming of the upper layers.

At the end of August 2011, the shallow inner part of the Kanin section had a positive temperature anomaly of $0.8^{\circ} \mathrm{C}$ in the 0 -bottom layer, which was $0.1^{\circ} \mathrm{C}$ higher than in 2010 . The outer part had a positive temperature anomaly of $0.7^{\circ} \mathrm{C}$ in the $0-200 \mathrm{~m}$, which was 0.6 ${ }^{\circ} \mathrm{C}$ lower than in 2010.

### 2.1.2 Horizontal distribution of water masses

Horizontal distributions of temperature and salinity are shown for depths of $0,50,100 \mathrm{~m}$ and near the bottom in Figures 2.1.2-2.1.9, and anomalies of temperature at the surface and near the bottom are presented in Figures 2.1.10-2.1.11. Anomalies have been calculated using the long-term means for the period 1929-2007.

As usual, the temperature near the surface gradually decreased northwards and temperatures below $0{ }^{\circ} \mathrm{C}$ were observed only in the far northern surveyed areas (Figure 2.1.2). Compared to earlier observations the surface temperatures were both higher $\left(1.7-2.6^{\circ} \mathrm{C}\right)$ than in 2010 and higher $\left(1.1-1.9^{\circ} \mathrm{C}\right)$ than the long-term mean. This shows that the summer heating of the surface this year has been much more than normal, or less extensive downward mixing has taken place. The only area with negative surface anomalies ( $<-0.5^{\circ} \mathrm{C}$ ) was west of the Spitsbergen/Svalbard Archipelago (Figure. 2.1.10).

Arctic waters were, as usual, most dominant in 50 m depth north of $76^{\circ} \mathrm{N}$ (Figure 2.1.4). At the 50 m depth the temperatures were mainly higher $\left(0.1-0.8^{\circ} \mathrm{C}\right)$ than normal but lower (by $0.1-1.3^{\circ} \mathrm{C}$ ) than in 2010.

In 100 m depth and close to the bottom, only small areas with temperatures below $-1^{\circ} \mathrm{C}$ were observed (Figure 2.1.6 and 2.1.8). The temperatures in the depths below 100 m were in general close to those in 2010, and still above the long-term mean $\left(0.2-0.7^{\circ} \mathrm{C}\right)$ in most of the Barents Sea (Figure 2.1.11). The high temperature in the Barents Sea is mostly due to the inflow of water masses with high temperatures from the Norwegian Sea and due to more intensive summer heating of the upper layer of the sea. During the last 9 years the inflow to the Barents Sea has been warm.

### 2.2 Distribution and abundance of 0-group fish

The distribution of eleven 0 -group fish species (capelin, cod, haddock, herring, polar cod, saithe, redfishes, Greenland halibut, long rough dab, wolffish, sand eel) are shown in Figs 2.2.1-2.2.11 and Gonatus - in Figure 2.2.12. The density grading in the figures is based on the catches, measured as number of fish per square nautical mile. More intensive colouring indicates denser concentrations. Abundance indices calculated for most ecologically important species (capelin, cod, haddock, herring, polar cod, saithe, redfishes, Greenland halibut and long rough dab) from 1980-2011 are shown in Tables 2.2.1-2.2.2. Length frequency distributions of the main species are given in Table 2.2.3. Biomass indices of 0 group capelin, cod, haddock and herring for 1993-2009, were calculated from abundance indices corrected for capture efficiency (Eriksen et al. 2011) and presented in Table 2.2.4.

The 2011 year class of cod is the highest on record, 0 -group capelin and haddock were also found to be strong year classes. The 2011 year classes of herring, redfish, saithe and long rough dab are poor, while polar cod is slightly above, and Greenland halibut is somewhat below, the long term mean level. The total biomass of four most abundant 0 -group fish (cod, haddock, herring and capelin) reach 2.5 million tonnes in August-September.

### 2.2.1 Capelin (Mallotus villosus)

Capelin were distributed over a wide area - from the Norwegian and Russian coast until $79^{\circ} \mathrm{N}$ and between $15^{\circ} \mathrm{E}$ and $57^{\circ} \mathrm{E}$ (Figure 2.2.1). The dense concentrations were observed in the southeastern area (between $70-73^{\circ} \mathrm{N}, 33-43^{\circ} \mathrm{E}$ ) and to the east of Hope Island. The boundary of capelin distribution was not found in the north, east, south and west.

Fish otoliths were taken at stations when it was difficult to separate of 0 -group capelin from older fish. In most samples (about 70\%) length of 0-group capein were between 4.0 and 5.5 cm , with an average of 4.6 cm , that is some smaller than the long term mean length ( 4.8 cm ). Very small capelin with length about 3 cm (Table 2.2.3) were found to the northeast from the Kildin Island (Murman coast), what indicate that summer spawning has taken place in this area.

The calculated density varied from 174 to 65 million fish per square nautical mile. Mean catch per trawl was 2150 fish.

The 2011 year class is strong year class. The 0 -group capelin biomass was about 228 thousand tonnes, and this is much higher than the long term mean (for period 1993-2011). The capelin biomass is shown in Table 2.2.4.

### 2.2.2 Cod (Gadus morhua)

0 -group cod were distributed over a wide area, except eastern and southeastern parts along Novaya Zemlya (Figure 2.2.2). The main dense concentrations were registered in the central part of the sea between $72^{\circ} \mathrm{N}-76^{\circ} \mathrm{N}$ and $20^{\circ}-35^{\circ} \mathrm{E}$, and to the southwest of Spitsbergen/Svalbard. Scattered registrations were observed further north than in the previous years, and were found along western and northern coast of the Spitsbergen/Svalbard up to $82^{\circ} \mathrm{N}$. Along the Novaya Zemlya and in the southeastern part of the Barents Sea 0 -group cod was observed only in the bottom trawls, that indicates more early their bottom settlement in this region. Although the densities of cod from bottom component at these stations was not higher than 30 fish per square nautical mile, and therefore have no influence on abundance index.

The fish length of 0 -group cod were between 5 and 11 cm . Most of the fish were between 6.5 and 9.5 cm , with mean length of 8.0 cm (Table 2.2.3). The mean length was lower than in 2010 but was higher than the long term mean. Good fish growth in autumn may indicate suitable feeding condition during first months of fish life.

The highest calculated density was about 21 million fish per square nautical mile, which is 4 times higher than in 2010. Mean catch was 1664 fish per trawl haul.

The abundance index of 2011 year-class is record high and much higher than 1995 year class, which dominated in the fishery over the long time. Therefore, the 2011 year class will probably add strong recruitment to the fishery from 2014. The 0 -group cod biomass was also record high; about 2 million tonnes (Table 2.2.4).

### 2.2.3 Haddock (Melanogrammus aeglefinus)

The occupation area of 0 -group haddock was found in the central and western areas of the Barents Sea and to the west and north of the Spitsbergen/Svalbard. To the east of $39^{\circ}$ E 0group haddock were not observed (Figure 2.2.3).

Length of 0 -group haddock varied between 3.9 and 16.0 cm and length of most fish was between 9.0 and 11.0 cm (Table 2.2.3). Mean length of haddock was 10.1 cm , which is higher than the long term mean. Larger growth of fish indicates suitable feeding conditions this year. Small 0-group haddock with mean length of 3.9-5.5 cm were found in the north and northwest of Spitsbergen/Svalbard, indicating late spawning of haddock.

The calculated density varied from 174 to 732 thousand fish per square nautical mile. Mean catch per trawl was 107 fish, which is higher than in 2010.

The 2011 year class is almost twice as high as the long term mean level, and can be characterized as strong. Since 2004 several strong year classes occurred, the 2005 year class being the strongest. These year classes may secure the fishery for years to come. The 0 -group haddock biomass was about 215 thousand tonnes that is higher than the long term mean (for period 1993-2011); (Table 2.2.4).

### 2.2.4 Herring (Clupea harengus)

0 -group herring were distributed in the south, central and western parts of the Barents Sea. The occupation area of herring was much smaller than in previous years, although somewhat larger than in 2010. The main dense concentration of herring were located between $72-75^{\circ} \mathrm{N}$ and $30-35^{\circ}$ E (Figure2.2.4). Scattered concentrations were observed along the Norwegian and Murman coast and between Spitsbergen/Svalbard and Bear Island.

Mean length of herring was 6.9 cm , and this is somewhat lower than in previous years. The length of herring varied between 3.5 and 11.0 cm , and most of the fish were $6.0-8.0 \mathrm{~cm}$ long (Table 2.2.3). The smaller fish were found along northeast of Murman coast, and were not larger than 5 cm .

Mean catch per trawl haul was 185 fish, which is lower than in 2007-2010. The calculated density varied from 134 to 1.4 million fish per square nautical mile.

The 0 -group herring biomass was very low; 151 thousand tonnes (Table 2.2.4). This is about 5 times lower than the long-term mean (for period 1993-2011).

The 2011 year-class of herring is lower than the average level, and therefore can be characterized as poor. Since 2004 no strong year classes has been observed, and low herring abundance may negatively influence the recruitment to the fishable stock.

### 2.2.5 Polar cod (Boreogadus saida)

In 2011 the distribution of 0-group polar cod was split into two components. Eastern component distributed along western coast of the Novaja Zemlya and western component allocated around Spitsbergen/Svalbard (Figure 2.2.5). Densest concentrations were observed close to the coast of Novaja Zemlya, while around Spitsbergen/Svalbard only scattered concentrations were found. Very small polar cod with length about 3 cm were found to the east from Spitsbergen/Svalbard, which indicate that spawning has taken place in this area.

The abundance indices for both components were calculated separately. Abundance of eastern component was at the long term average level, while abundance index of western component was about 4.5 times lower.

The mean length of 0 -group polar cod was 4.9 cm , and was higher than in the last three years and the long term mean of 3.9 cm . Most of the fish had lengths between 4.5 and 6.0 cm (Table 2.2.3).

During survey 0 -group polar cod distributed further north and east than the surveyed area and only a part of the total distribution was covered.

### 2.2.6 Saithe (Pollachius virens)

The 0 -group saithe was found on local stations in the central and western parts of the Barents Sea (Figure 2.2.6).

Length of 0-group saithe varied between 6.5 and 14.5 cm , and most of fish (about 60\%) was between 7.0 and 7.5 cm . Mean length of saithe was 8.4 cm and was lower than in 2010 and the long term mean of 9.1 cm (Table 2.2.3).
The maximum of calculated density reached 12.7 thousand fish per nautical mile and the maximal catch was 59 fish only. Both density and catch rates were much lower than in previous years.

Since 2005 (except 2010) abundance indices of 0-group saithe were lower than the long term average. The 2011 year class is also about 9 times lower than the long term mean and therefore the 2011 year-class of saithe in the Barents Sea may be characterized as poor.

### 2.2.7 Redfishes (Sebastes sp.)

0 -group redfish was observed in the western part of the Barents Sea (Figure 2.2.7). The distribution area and dense concentrations were smaller than in 2009-2010.

In 2011 the mean fish length was 4.0 cm , which is lower than in 2010, but somewhat higher than the long term mean ( 3.8 cm ). Relatively large 0 -group redfish in this year indicated better-than-average feeding condition during the first months of its life.

Mean catch per trawl haul was 109 fish. The calculated average density reached 18.5 million fish per square nautical mile.

The abundance of 0 -group redfish is about 9 times lower than the long term average. So the 2011 year-class can be characterized as very poor.

### 2.2.8 Greenland halibut (Reinhardtius hippoglossoides)

As in previous four years, 0 -group Greenland halibut were found in very low densities and in small areas north, west and south of Spitsbergen/Svalbard (Figure 2.2.8). Greenland halibut starts to settle to the bottom before the ecosystem cruise is carried out, and there might be a strong variation in the timing of larvae settling. Therefore the calculated 0 -group Greenland halibut is probably not reflecting the real year-class strength.

Fish length varied between 4.0 and 9.5 cm , while most of fish were between 5.5 and 7.5 cm . The mean length of fish was 6.4 cm , which was close to the long term mean (Table 2.2.3).

Calculated density concentration reached 3.7 thousand fish per square nautical mile while an average is 72.5 fish per square nautical mile.

Since 2007 abundance of Greenland halibut continuously increased, but index of 2011 yearclass not yet reached the long term average.

### 2.2.9 Long rough dab (Hippoglossoides platessoides)

Long rough dab were distributed in several local areas of the Barents Sea (Figure 2.2.9). Dense concentrations of 0-group long rough dab were not observed.

Mean length of fish was 3.7 cm which is the highest since 2005. In most catches fish lengths between 3.0 and 4.5 cm dominated (Table 2.2.3). Mean catch was lower than in 2010, and only some catches reached up to 65 fish. The calculated mean density was 162 fish per square nautical mile.

The 2011 year-class of long rough dab is approximately 10 times lower than the long term mean and lowest since 2005. The year class is characterized as very poor.

### 2.2.10 Wolffishes (Anarhichas sp.)

There are three species of wolffish found in the Barents Sea: Atlantic wolffish (Anarhichas lupus), spotted wolffish (Anarhichas minor) and northern wolffish (Anarhichas denticulatus). Due to uncertainty in species identification at the 0 -group stage it was decided to combine the species into a larger group (Genus) during the 0 -group investigations.

In total 0 -group wolffish were found in scattered distribution to the north and south of Spitsbergen/Svalbard (Figure 2.2.10).

The calculated mean density was about 74 fish per square nautical mile, which was lower than in 2008-2010. No index is calculated for this species.

### 2.2.11 Sandeel (Ammodytes sp.)

In the Barents Sea Ammodytidae are represented by Ammodytes marinus which is distributed along the Norwegian coast, and Ammodytes tobianus which distributed in the southeast and between Novaya Zemlya and Bear Island. Due to uncertainty in species identification at the 0 group stage it was decided to combine species into larger groups (Genus).

0-group sandeel were found in south-eastern part of the Barents Sea and around Bear Island (Figure 2.2.11).

Mean catch was 13 fish per trawl haul. The calculated density reached 158 thousand fish per square nautical mile with an average of 78 fish per square nautical mile. This is lower than in 2008-2010. No index was calculated for this species.

### 2.2.12 Gonatus fabricii

In the Barents Sea Gonatus fabricii is observed in the pelagic water layer. In 2011 Gonatus was distributed in the western part of the Barents Sea (Figure 2.2.12).

Mean catch was 13 individuals per trawl haul. The calculated density reached 16.7 thousand individuals per square nautical mile with an average of 357 fish per square nautical mile. No index was calculated for this species.

### 2.3 Distribution and abundance of pelagic fish

Number of fish sampled during the survey is presented in Appendix 2.

### 2.3.1 Capelin (Mallotus villosus)

## Distribution

The geographical density distribution of capelin at age $1+$ and for the total stock are shown in Figures 2.3.1 and 2.3.2. The total distribution area of capelin was wider than in last year, and differed also in other respects, but the overall distribution resembled quite closely that found in 2008-2010. In 2011, very little capelin were detected in the areas to the west of Spitsbergen/Svalbard, and practically no capelin north of Spitsbergen/Svalbard. However, the distribution area reached further to the north in the areas east of $40^{\circ} \mathrm{E}$, and contrasting the distribution in most years during the last three decades, quite dense concentrations were found north of $77^{\circ} \mathrm{N}$ and east of $50^{\circ} \mathrm{E}$. The main dense concentrations were found to the north-east of the Hopen island and northwards to beyond the King Karls Land, and the dense concentrations continued eastward to about $58^{\circ}$ E. Some capelin schools were observed until the Kara sea (St. Anna Trough) above the 400 m depth and it is absolutely northeastern distribution record during all research period.

Young capelin were mainly found to the south of $77^{\circ} \mathrm{N}$, and dense concentrations were located eastward of the Hopen island stretching south-eastwards in the Central Bank. Sample echograms of capelin distribution in the northern area are shown in Figures 2.3.3-2.3.5.

## Abundance estimate and size by age

A detailed stock size estimate is given in Appendix Table 1, and the time series of abundance estimates is summarized in Appendix Table 2. The main results of the abundance estimation in 2011 are summarized in the text table below. The 2010 estimate is shown on a shaded background for comparison.

Summary of stock size estimates for capelin

| Year class |  | Age | Number ( $10^{9}$ ) |  | Mean weight (g) |  | Biomass ( $10^{3} \mathrm{t}$ ) |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2010 | 2009 | 1 | 209.6 | 247.8 | 2.4 | 3.0 | 495.9 | 740.8 |
| 2009 | 2008 | 2 | 181.2 | 127.9 | 9.7 | 10.2 | 1764.0 | 1305.0 |
| 2008 | 2007 | 3 | 55.3 | 60.9 | 21.9 | 23.4 | 1213.9 | 1426.9 |
| 2007 | 2006 | 4 | 8.0 | 0.9 | 29.1 | 26.3 | 233.7 | 23.5 |
| Total stock in: |  | 1-4 | 454.1 |  | 8.2 |  | 3707.7 |  |
| 2011 | 2010 |  |  | 437.5 |  | 8.0 |  | 3496.4 |

The total stock is estimated at about 3.7 million tonnes. It is about $6 \%$ higher than the stock estimated last year and higher than the long term mean level. About $57 \%$ ( 2.1 million tonnes) of this stock is above 14 cm and considered to be maturing. The 2010 year class (1-group) consists, according to this estimate, of about 210 billion individuals. This estimate is somewhat lower than that obtained for the 1- group last year, but is slightly above the longterm mean. The mean weight $(2.4 \mathrm{~g})$ is 0.6 g lower than that measured last year, and 1.2 g below the long-term average. The biomass of the 2010 year class is about 0.5 million tonnes, which is $33 \%$ lower than one year olds in last year and below the long term mean. It should be kept in mind that, given the limitations of the acoustic method concerning mixed concentrations of small capelin and 0 -group fish and near-surface distribution, the 1 -group estimate might be more uncertain than that for older capelin.

The estimated number of the 2009 year class (2-group) is about 181 billion, which is about 1.4 times the size of the 2008 year class measured last year. Consequently the biomass of the two years old fish is about 1.8 million tonnes. The mean weight at this age is 9.7 g , which is lower than in last year ( 10.2 g ), and is one gram below the long-term average (Table 2.3.2).

The 2008 year class is estimated at about 55 billion individuals, which is slightly below the three-year-olds last year. This age group with mean weight 21.9 g (about 1.5 g below the long-term average) has a biomass of about 1.2 million tonnes, which is well above the longterm average. The 2007 year class (now 4 years old) is estimated at 8 billion individuals. With a mean weight of 29.1 g this age group makes up about 234 thousand tonnes, which is 10 times higher than last year, and above the long term average. Practically no capelin older than four years was found.

The capelin stock size estimate is used as input to the stock assessment and prognosis model for capelin (CapTool). The mature part of the stock is basis for the prognosis of spawning stock in spring 2012, where also mortality induced by predation enters into the calculations. The work concerning assessment and quota advice for capelin is dealt with in a separate report that will form part of the ICES Arctic Fisheries Working Group report for 2012.

## Total mortality calculated from surveys

Table 2.3.3 shows the number of fish in the various year classes, and their "survey mortality" from age one to age two. As there has been no fishing on these age groups, the figures for total mortality constitute natural mortality ( M ) only. The estimates of $M$ have varied considerably, and within survey uncertainties reflect quite well the predation on capelin. From 2006, the natural mortality started to decrease. In 2010 the M was estimated to a small negative value, as it was for the year classes 1992, 1994, and 2006, This shows that either the one-group are underestimated or the two-group is overestimated these years. Knowing that the measurement of the 1 -group is more uncertain than the older age groups due to limitations in the acoustic method, the first mentioned possibility is the most probable. In 2011 the survey mortality was estimated at $27 \%$.

### 2.3.2 Polar cod (Boreogadus saida)

## Distribution

As in the previous year, the polar cod distribution in the Barents Sea was almost completely covered. The polar cod stock was widely distributed in the northern and eastern parts of the Barents Sea and adjoining part of the Kara Sea (to the north of Novaja Zemlja). The geographical density distribution for fish at age 1+ and for the total stock are shown in Figs. 2.3.6 and 2.3.7. The main concentrations of adult fish were found along west coast of Novaja Zemlja and northward toward Franz Josef Land. Small areas of scattered concentrations were observed to the west and to the east of Spitsbergen/Svalbard. Figure 2.3 .8 shows a typical acoustic registration of polar cod near the Novaja Zemlja.

## Abundance estimation

The stock abundance estimate by age, number, and weight was calculated using the same computer program as for capelin.

A detailed estimate is given in Table 2.3.4, and the time series of abundance estimates is summarized in Table 2.3.5. The main results of the abundance in 2011 are summarized in the text table below. The 2010 estimate is shown on a shaded background for comparison.

Summary of stock size estimates for polar cod

| Year class |  | Age | Number $\left(10^{9}\right)$ |  | Mean weight $(\mathrm{g})$ |  | Biomass $\left(10^{3} \mathrm{t}\right)$ |  |
| :--- | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 2010 | 2009 | 1 | 34.5 | 27.3 | 8.2 | 8.6 | 282.3 | 234.2 |
| 2009 | 2008 | 2 | 14.5 | 18.3 | 21.1 | 29.7 | 304.4 | 543.1 |
| 2008 | 2007 | 3 | 4.7 | 13.0 | 50.1 | 45.8 | 237.1 | 594.6 |
| 2007 | 2006 | 4 | 0.5 | 1.3 | 71.3 | 46.8 | 36.7 | 58.6 |
| Total stock in:   <br> 2011 2010 $1-4$ |  | 54.2 | 59.8 | 15.9 | 23.9 | 860.5 | 1430.5 |  |

Based on TS value: $21.8 \log \mathrm{~L}-72.7$, corresponding to $\sigma=6.7 \cdot 10^{7} \cdot \mathrm{~L}^{2.18}$

The number of individuals in the 2010 year-class (the one-year-olds) is $25 \%$ higher than the one-group measured last year. The mean weight a bit lower, and therefore, the biomass of one-year-olds is $20 \%$ higher compared to last year. The abundance of the 2009 year class (the two-year-olds) is 14.5 billions. This is almost $20 \%$ lower than the two-group found last year and moreover, the mean weight was 8.6 g lower. The biomass, therefore, was reduced significantly compared to the 2008 year-class estimated last year. Also the three-years-old fish (2008 year class) is reduced by more than $60 \%$ by number compared to the three-group estimated last year. The mean weight is, however higher, and the biomass of this age group is 2.5 times lower than that for the corresponding age group during the 2010 survey. The four-year-olds (2007 year class) are scarcely found, but have a much higher mean weight than the four-year-olds had last year. No fish of age 5 or higher were found. The total stock, estimated at 0.9 million tonnes, is reduced by $40 \%$ compared to that found in 2010.

## Total mortality calculated from surveys

Table 2.3.6 shows the "survey-mortality rates" of polar cod in the period 1985 to 2011. The mortality estimates are unstable during the whole period. Although unstable mortalities may indicate errors in the stock size estimation from year to year due to incomplete coverage and other reasons, the impression remains that there is a considerable total mortality on young polar cod. Prior to 1993, these mortality estimates represent natural mortality only, as practically no fishing took place. In the period 1993 to 2006 catches were at a level between 1 and 50000 tonnes. Since there has been a minimum landing size of 13 cm in that fishery, a considerable amount of this could consist of two- and even one-year-olds, and this may explain some, but only a small part of the high total mortality. From 2003 to 2004, 2006-2007 and 2009-2010 there are negative survey mortalities for age groups 1-2 and in 1998-1999 with 2003-2004 also for age group 2-3, confirming the impression expressed previously that in some years the estimate for various reasons were underestimates. Apart from these years, the survey mortalities have been quite stable in recent period.

### 2.3.3 Herring (Clupea harengus)

In the Barents Sea only young Norwegian spring spawning (NSS) herring is present, although some older herring may be found outside the coast of western Finnmark. At age 3-4 the herring migrates to the Norwegian Sea, where it spends the rest of the adult life. The young herring have very big fluctuation and abrupt changes in numbers in the Barents Sea.

In some cases it is difficult to assess the young herring stock size during autumn. The main problem is in distribution of herring schools close to the surface, above the range of the echo sounders. It is also problematic to get representative sampling of fish schooling near the surface.

## Distribution

This year, only very scattered concentrations of herring were found along the coast of Finnmark and Kola (Figure 2.3.9). Herring in age groups 1-3 was registered but the two-yearolds dominated.

## Abundance estimation

The estimated number and biomass of western and eastern components of NSS herring for total age- and length groups are given in Table 2.3.7. The time series of estimates is shown in Table 2.3.8. In the text table below the main results of the abundance estimation in 2011 are summarized for young herring only (1-4 years old). The 2010 estimate is shown on a shaded background for comparison. It is noted that because of insufficient sampling of herring, this estimate divided on age-groups should be considered highly uncertain.

The total abundance of herring aged 1-4 covered during the survey was estimated at $1.6 \cdot 10^{9}$ specimens (about $13 \%$ lower than the value estimated in 2010). The biomass of $0.11 \cdot 10^{6} \mathrm{t}$ is $29 \%$ lower than what was found in 2010. The same year class totally dominated both in last year and this year. During recent years, the amount of young herring entering the Barents Sea
has steadily decreased (table 2.3.8), and the estimated stock size in 2011 is only about $10 \%$ of the average stock size during the period 1999 to 2011.

Summary of abundance estimates of the portion of the herring stock found in the Barents Sea

| Year class |  | Age | Number $\left(10^{9}\right)$ |  | Mean weight $(\mathrm{g})$ |  | Biomass $\left(10^{3} \mathrm{t}\right)$ |  |
| :--- | :--- | :---: | :---: | :---: | :---: | :---: | :---: | ---: |
| 2010 | 2009 | 1 | 0.09 | 1.047 | 30.4 | 32.9 | 2.9 | 34.5 |
| 2009 | 2008 | 2 | 1.50 | 0.315 | 70.2 | 106.9 | 105.5 | 33.7 |
| 2008 | 2007 | 3 | 0.01 | 0.234 | 126.0 | 157.7 | 0.8 | 37.0 |
| 2007 | 2006 | 4 | 0 | 0.251 | - | 191.1 | 0 | 48.1 |
| Total stock in: |  |  |  |  |  |  |  |  |
| 2011 | 2010 | $1-4$ | 1.61 | 1.847 | 68.0 | 82.8 | 109.2 | 153.3 |

Based on TS value: $20.0 \log \mathrm{~L}-71.9$, corresponding to $\sigma=8.1 \cdot 10-7 \cdot \mathrm{~L} 2.00$

### 2.3.4 Blue whiting (Micromesistius poutassou)

In the western part of the Barents Sea blue whiting were observed as in previous years. The target strength used for blue whiting is uncertain, and the estimate should to a greater extent than the other estimates be considered as a relative quantity only.

## Distribution

The distribution of blue whiting (all age groups) is shown in Figure 2.3.10. As in previous years the distribution area stretches eastward from the western boarder of the covered area up to $30^{\circ} \mathrm{E}$ and from northern coast of Norway up to $77^{\circ} \mathrm{N}$ to the west of Spitsbergen/Svalbard.

## Abundance estimation

The estimated number and biomass of blue whiting per age- and length group is given in Table 2.3.9. Total abundance was estimated to be $0.6 \cdot 10^{9}$ individual fish and the biomass to $0.130 \cdot 10^{6} \mathrm{t}$. Since 2003-2004, when more than one million tonnes of blue whiting was found in this area, there has been a steady decrease in biomass (Table 2.3.10), and the age distribution has been shifted towards older fish. The main bulk of this stock component in 2011 consisted of 2004-2006 year-classes at age 5-7. Older fish were found in smaller quantities and only small numbers of fish younger than 4 years old were found.

### 2.4 Distribution and abundance of demersal fish

Figs. 2.1-2.13 shows the distribution of demersal fish. Numbers of fish sampled during the survey are presented in Appendix 2. Preliminary estimation of abundance and biomass of main demersal fish are presented in Table 2.4. Final results will be presented after age reading.

### 2.4.1 Cod (Gadus morhua)

The distribution area of cod in the Barents Sea (Figure 2.4.1) was completely covered. At this time of the year, towards the end of the feeding period, the distribution of cod is wide. Cod reach the limits of its natural habitat and could spread far north, east and northeast. Total distribution of cod was similar to 2010, but it stretched even further northwards. There were
several observations north of Spitsbergen/Svalbard and such high abundance has never been found to the north of $80^{\circ} \mathrm{N}$. The main concentrations were observed in two areas: one was to the west and south-west of the Novaja Zemlja archipelago, and the other one was in the central and northern parts of the Barents Sea. The main biomass of cod was concentrated in the depth range from 50 m down to $250 \mathrm{~m}(74 \%)$. The abundance indices divided on age groups for the period since 2004 are shown in Table 2.4.2.

### 2.4.2 Haddock (Melanogrammus aeglefinus)

The haddock distribution (Figure 2.4.2) was very similar to last year observation, but to the north of Spitsbergen/Svalbard it was found more often. Haddock were distributed in a large area from Norwegian and Russian coast up to $81^{\circ} \mathrm{N}$ and as far east as $57^{\circ} \mathrm{E}$ in south-eastern Barents Sea. The main concentrations of haddock were found around Bear Island and in shallow areas in the south-eastern part of the Barents Sea which coincide with the distribution in 2010 and 2009. The preliminary abundance and biomass estimates show a strong reduction from the 2010 estimates (see table below). The greatest concentrations ( $76 \%$ of total) were distributed in depths down to 100 m . The abundance indices divided on age groups for the period since 2004 are shown in Table 2.4.3.

### 2.4.3 Saithe (Pollachius virens)

During survey only a small part of saithe distribution has covered Saithe were mostly caught along the northern coast of Norway to the west of $25^{\circ} \mathrm{E}$ (Figure 2.4.3). $90 \%$ of the observations were found in the depth range $150-250 \mathrm{~m}$. The main distribution of saithe in 2011 coincides with the distributions in 2010 and 2009.

### 2.4.4 Greenland halibut (Reinhardtius hippoglossoides)

During survey mainly young age groups of Greenland halibut were observed. The adult part of the stock was distributed outside of the survey area. Greenland halibut were distributed in traditional areas along the shelf slope in the western Barents Sea, in deeper areas of the Barents Sea, in the deeper part around Spitsbergen/Svalbard and Franz Josef Land and in the northern part of the Kara Sea (Figure 2.4.4). The main biomass (77 \%) of Greenland halibut has been concentrated in the depth range from 250 m to 550 m .

### 2.4.5 Golden redfish (Sebastes norvegicus)

Golden redfish were distributed in the same part of the Barents Sea basin as in previous years. The main densities were observed along the shelf slope to the north and west of Spitsbergen/Svalbard and in deeper waters in the south-western part of the Barents Sea (Figure 2.4.5). The main part ( $66 \%$ ) was concentrated at depths from 150 down to 300 meters.

### 2.4.6 Deep-water redfish (Sebastes mentella)

The main concentrations of deep-water redfish were distributed in traditional areas and were found in western and north-western parts of the Barents Sea, and to the west of Spitsbergen/Svalbard (Figure 2.4.6). Mainly young age groups of Sebastes mentella were
found in deep-water zones in the eastern part of the Barents Sea. The main biomass of Deepwater redfish ( $95 \%$ ) was concentrated in the depth range from 250 m down to 500 m .

### 2.4.7 Norway redfish (Sebastes viviparus)

Norway redfish were distributed in the south-western part of the Barents Sea (Figure 2.4.7). The main biomass of Norway redfish ( $95 \%$ ) concentrated at depths from 200 m down to 350 m.

### 2.4.8 Long rough dab (Hippoglossoides platessoides)

As in previous years, long rough dab was found in all surveyed areas and the catches were generally high (Figure 2.4.8). Catches of long rough dab were taken as far east as $77^{\circ} \mathrm{E}$ and north of $80^{\circ} \mathrm{N}$ in area of Saint Anna trench. The greatest catches of long rough dab were in an area stretching from eastern coast of Spitsbergen/Svalbard to the south-western coast of Novaja Zemlja. The main biomass of long rough dab (64\%) concentrated in the depth range from 150 m down to 300 m .

### 2.4.9 Wolffishes (Anarhichas spp)

The greatest catches of Atlantic wolffish (Anarhichas lupus) were to the south from Spitsbergen/Svalbard, near Bear Island, and on shallow sites in the southern part of the Barents Sea (Figure 2.4.9). The main biomass of Atlantic wolffish (70\%) was concentrated in the depth range from 100 m down to 200 m .

Spotted wolffish (Anarhichas minor) was distributed similar to that observed in 2010, but was more abundant. The greatest catches of Spotted wolffish were to the east from Bear Island, and on shallow sites in the southeastern and in the central parts of the Barents Sea (Figure 2.4.10). The main biomass of Spotted wolffish ( $60 \%$ ) was concentrated in a range of depths from 100 m down to 200 m .

The distribution of Northern wolffish (Anarhichas denticulatus) was similar to that observed in 2009 and 2010, but was more abundant. Most concentrations were located in the central areas (Figure 2.4.11). The main part of the catches ( $67 \%$ ) were in the depth range $250-400 \mathrm{~m}$.

### 2.4.10 Plaice (Pleuronectes platessa)

Plaice was mainly distributed ( $73 \%$ of total) in the depth range from 50 down to 100 m to the northwest from Kanin peninsula (Figure 2.4.12).

### 2.4.11 Norway pout (Trisopterus esmarkii)

The main concentrations of Norway pout were observed in the south-western part of the Barents Sea (Figure 2.4.13). In some trawl stations Norway pout were observed to the west and north of Spitsbergen/Svalbard, as far north as $81^{\circ} \mathrm{N}$, which is $2^{\circ} \mathrm{N}$ further north than observed in 2010. In the southern part of the Barents Sea Norway pout were distributed eastward until $40^{\circ} \mathrm{E}$. The main biomass of Norway pout ( $95 \%$ ) was concentrated in the depth range from 150 m down to 350 m .

### 2.4.12 Non target fish species

Some species were chosen as indicator species to demonstrate the distribution patterns of fishes from the different zoogeographic groups: the Thorny skate (Amblyraja radiata) and Northern skate (Amblyraja hyperborea) (Figs. 2.4.14-2.4.15).

## Thorny skate (Amblyraja radiata), boreal zoogeographic group

As in 2009 and 2010, this species was quite widely distributed in the Barents Sea excluding southeastern and northeastern regions (Figure 2.4.14). Most large catches were in the central area, around Bear Island, to the west of Spitsbergen/Svalbard and on shallow sites in the southeast corner of the Barents Sea. Catches of thorny skate were more common to the north and northeast of Spitsbergen/Svalbard this year than in previous years. The Thorny skate preferred to stay in a wide range of depths from 50 m down to $150 \mathrm{~m}(44 \%$ of total was found there).

## Northern skate (Amblyraja hyperborea), arctic zoogeographic group

Northern skate was distributed in the deeper waters of the eastern Barents Sea and in the trench of Saint Anna (Figure 2.4.15). The main catches were from range of depths from 200 m down to 350 m ( $57 \%$ of total).

### 2.5 Ecological interactions

### 2.5.1 The effect of bottom temperature and depth on the distribution of cod and haddock and their biological parameters within these ranges

When comparing 2011 with 2010, the area with bottom temperatures between 0 and $1^{\circ} \mathrm{C}$ have increased considerably while the area, with temperature above $3^{\circ} \mathrm{C}$, have decreased (red lines in Figures 2.5.1 and 2.5.2).

Characteristic to the cod distribution in August-September 2011 was that the largest catches of $\operatorname{cod}(\sim 140 \mathrm{~kg}$ in average per nautical mile) were recorded in areas with a temperature range of 0-2 C (blue lines in Figure 2.6.1). In 2010 the catches were highest in areas with a temperature range from $-1^{\circ} \mathrm{C}$ to $1^{\circ} \mathrm{C}(\sim 150 \mathrm{~kg}$ in average per nautical mile). In 2010, larger catches was taken in areas with bottom temperatures $2-4{ }^{\circ} \mathrm{C}$ when compared to 2011 , and lower catches was taken in 2010 in areas where the temperature range was from $-1^{\circ} \mathrm{C}$ to $0^{\circ} \mathrm{C}$ when compared with 2011

For haddock (Figure 2.5.2) the largest catch was made in the temperature range $3-4^{\circ} \mathrm{C}$ in both 2010 and 2011. However, haddock mean catches were an order lower in 2011 when compared to 2010 .

Both mean length of the cod and the mean hepatosomatic index (the ratio of liver weight to body weight, providing an indication on status of energy reserve in an animal, in a poor environment, fish usually have a smaller liver) decreases with increasing temperatures (Figure 2.5.3). The hepatosomatic index of cod is highest (indicating good energy reserve) when the
temperature is below zero and where the cod most probably also feeds on capelin and polar cod.

In 2011 the largest mean length of haddock were found in the areas with bottom temperature of $1-2{ }^{\circ} \mathrm{C}$ (Figure 2.5.4). At the same time, the greatest hepatosomatic index was registered in the areas with $3-4^{\circ} \mathrm{C}$ temperature range where also the haddock catches were highest.

In 2010 most cod was found at $240-260 \mathrm{~m}$ depth (green circles in Figure 2.5.5), but in 2011 cod were more widely distributed by depth (green circles in Figure 2.5.6). For haddock there was not significant changes in haddock distribution by depth between 2010 (yellow triangles in fig 2.5.5) and 2011 (yellow triangles in fig 2.5.6). In 2011, large concentrations of cod and haddock were observed at $50-200 \mathrm{~m}$ depths, with bottom temperatures of $2-4{ }^{\circ} \mathrm{C}$.

### 2.6 Phyto- and zooplankton

Data on chlorophyll a, nutrients and phytoplankton species composition are now being processed and analyzed at the IMR and PINRO laboratories. A summary and some preliminary results will be presented in an electronic attachment after the data have been worked up in the laboratories.

The map of zooplankton sampling localities and sampling gear (Russian and Norwegian vessels) are shown in Figure 2.6.1. The main results of the zooplankton observations will be presented in an electronic attachment after the data have been worked up in the laboratories.

The figure indicates that the investigated area is covered very well as seen from the number of CTD stations (Figure 2.2) taken. A total of 221 WP2 net hauls were obtained by the Norwegian vessels "Christina E", "Johan Hjort" and "Helmer Hanssen". For the third time the area north of Spitsbergen/Svalbard was covered with respect to mesozooplankton distribution and abundance. Stratified sampling targeting slightly larger zooplankton (i.e. krill/amphipods) was conducted with the Mocness system, while a new Macroplankton trawl was operated in a double oblique haul from both "Christina E" and "Johan Hjort", particularly in the central and northern regions of the Barents Sea to obtain integrated samples of krill and amphipods to better assess their population structure. The WP2 vertical net coverage is very satisfactory and comparable to the years 2009 and 2010. In addition vertical hauls from 50 m depth to surface were conducted by a slightly modified WP3 net (inner diameter 118 cm , mesh size $1000 \mu \mathrm{~m}$, with a non-filtering cod-end) both on "Christina E" and "Johan Hjort" on a couple of occasions to obtain quantitative samples of cnidarians and ctenophores. The table below gives an overview of total zooplankton hauls for different types of zooplankton sampling gear during the Ecosystem survey.

Total number of plankton net hauls obtained during the Norwegian and Russian surveys in the Barents Sea in August-September 2011

| Net | Norwegian ships <br> «Christina E» |  | «J.Hjort» «Helmer Hanssen»» | «Vilnyus» |
| :--- | :--- | :--- | :--- | :--- |
| WP-2 | 67 | 94 | 60 | - |
| WP-3 | 4 | 2 | - | - |
| Juday | - | - | - | 241 |
| MOCNESS | - | 16 | - | - |
| Macroplankton trawl | 12 | 13 | - | - |
| BR* | - | - | - | 96 |
| Algae net | 15 | 24 | 23 |  |

* BR net: Macroplankton net with a $0.2 \mathrm{~m}^{2}$ opening and $564 \mu \mathrm{~m}$ mesh size

A map of the zooplankton biomass distribution based on Norwegian data is shown in Fig 2.6.1. From the Norwegian data, sampled in the western part it is evident that a greater region of the Barents Sea has very low biomass in 2011, similar to what was observed in 2009 and 2010 (not shown in this report). There is evidence of distinctly higher biomass regions south of Spitzbergen and between the Bear island and Norwegian mainland. The average zooplankton biomass in 2011, based only on Norwegian data (i.e. the western half of the Barents Sea, excluding the area west and north of Spitsbergen/Svalbard) is $6.05 \mathrm{~g} / \mathrm{m}^{2}$, compared to $5.87 \mathrm{~g} / \mathrm{m}^{2}$ for 2009 and $6.6 \mathrm{~g} / \mathrm{m}^{2}$ for 2010 . A particular feature are scattered higher biomass regions associated with west Spitsbergen/Svalbard fjords. The average biomass around the Spitsbergen/Svalbard archipelago, $7.04 \mathrm{~g} / \mathrm{m}^{2}$, is somewhat higher compared to the standard area of the central Barents Sea. These data are compiled from the research vessel "Helmer Hanssen" only.

According to the Russian data (i.e. the eastern half of the Barents Sea), the highest biomass were observed in the central part of the sea. However, because of limited availability of sampling in the north there was no Russian data on the condition of zooplankton for this part of the sea. In the northern areas the basic biomass is formed of the Arctic species.

From the Norwegian vessel "Christina E" a total of 67 WP-2 hauls (bottom-0 m) were conducted at 70 CTD stations. From the Norwegian vessels no Juday net was deployed during the ecosystem survey in 2011. Hauls conducted west of the 500 m depth contour at the entrance to the Barents Sea as well as $200-0 \mathrm{~m}$ net hauls where bottom depth significantly exceeds 200 m are not included. On "Johan Hjort" a total of 94 WP-2 hauls (bottom-0 m) were conducted. A total of 229 hauls from all three Norwegian ships satisfied the extraction criteria for the bottom-0m stratum, the region around Spitsbergen/Svalbard included.

Species composition, abundance and biomass from WP2 and Juday nets collected at the same stations in 2004 and 2005 have been partly analyzed and compared. Preliminary analysis has shown a significant variability in stage composition of key species of Calanus. Based on data
from 2004 and 2005, including Russian data from 2006 when present, a more extensive comparison and analysis are now being undertaken to help quantify this variability. The agreement on comparative collection of zooplankton samples by WP-2 and Juday net on Norwegian and Russian vessels will be followed up by both parties with regard to working up samples, exchange of raw data, analysis and publication in relevant reports, symposia or international refereed journals. It is suggested that current and past effort is strengthened with additional sampling and also new approaches in future surveys with the ultimate goal of a unified sampling approach.

In 2007, based on joint experience back to 2004, a dual WP2 and a Juday net system was taken in use for better performance and more efficient comparisons between the sampling gears. Preliminary results from this gear comparison exercise have already been obtained, but a more thorough analysis is still needed. Additional in situ comparisons with the dual net system are warranted as the total number of hauls at this stage is low (19) and therefore should be expanded to obtain a data set that can be explored statistically in a reliable manner. Such an approach implies a significant effort for both IMR and PINRO plankton laboratories and their scientists, and it must be carefully evaluated how much time and effort can be dedicated to such future work. Analysis of the currently available data might give answers to this. It should be an aim to present a more complete analysis of the dual-net as electronic attachment to the Joint Ecosystem Survey Report.

### 2.7 Marine mammals and seabirds

### 2.7.1 Marine mammals

The marine mammal observations are presented in Table 2.7.1. and Figure 2.7.1-2.7.3.

In total 2338 individuals of marine mammals, comprising 12 identified species, were observed in the Barents Sea during the ecosystem survey in 2011. This number amounts to about $70 \%$ of the number of individuals observed in 2010, when 14 species were observed. Species not observed this year, but was observed last year, include white whales and walrus.

Like in previous years, the most frequently observed marine mammal species was the whitebeaked dolphin (about $66 \%$ of the total numbers observed). White-beaked dolphins were distributed along the polar front, although a few observations were north of the front in the eastern Barents Sea. Among the toothed whales, also harbour porpoises, killer whales and sperm whales were observed. The harbour porpoises inhabited shallower areas in the southeastern Barents Sea, and killer whales were observed both in the northern and southern Barents Sea. The sperm whales were observed along the shelf edge. However, a few sperm whale observations were recorded far into the Barents Sea from Johan Hjort, but still in the deeper areas of the Bear Island Trough.

Among the baleen whales, blue, fin, humpback and minke whales were observed. The most frequently observed was the minke and humpback whales (about $9 \%$ of the marine mammal observations). Minke whales were observed with humpback and fin whales on shallow banks
north of the polar front, and towards Franz Joseph Land. Fin and minke whales were also observed in the south-western Barents Sea, as in previous years. However, minke whales were more frequently observed in the south-eastern Barents Sea than in previous years.

Also this year few harp seals ( 33 individuals) were observed, in the northern range limit of the Barents Sea, and some individuals in the Kara Sea. Two bearded and 1 ringed seal were observed north of Spitsbergen/Svalbard.

One polar bear was observed east of Franz Joseph Land, in the Kara Sea.

### 2.8 Seabirds

The observed birds from the participating Ecosystem vessels are shown in Table 2.7.2. The distribution of birds observed from the Norwegian vessels are shown in Figure 2.7.4 and 2.7.5.

### 2.9 Benthos

All four vessels involved in the ecosystem survey in 2011 recorded benthos and shellfish in bottom trawl hauls. A standard bottom trawl (Campelen-trawl) was used on all the vessels to cover the whole Barents Sea area (Fig 2.1). The invertebrate biomass varied from 6.9 g to 1752 kg between trawl hauls (standardised to 15 minutes), with maximum biomass recorded in the north eastern part.

### 2.9.1 Invertebrate benthos

The total biomass of all registered invertebrate catch (except northern shrimp, Pandalus borealis) was summarized per station and is presented in Figure 2.8.1.

The benthos biomass distribution in 2011 was generally the same as in previous years. The highest biomass ( 1369 and $1973 \mathrm{~kg} / \mathrm{nml}$ of sponges "Porifera") was recorded in the northern part of the Kara Sea in the Saint Anna trough. In the southwestern part of the Barents Sea up to 4 tons of Geodia (sponges) were recorded in previous years (2006-2009). But in this part of the Barents Sea, a dramatic reduction in catches was observed of this animal group in 2010 ( $235 \mathrm{~kg} / \mathrm{nml}$ ) and $2011(450 \mathrm{~kg} / \mathrm{nml})$. This might partly be caused by increased effort to avoid such catches. Another highest biomass catch in 2011 was of the brittle star Ophiocantha bidentata with $462 \mathrm{~kg} / \mathrm{nml}$.

The benthos was split into eight animal groups: Annelida, Bryozoa, Coelenterata, Crustacea, Echinodermata, Mollusca, Porifera and Varia. Their distribution patterns (Fig 2.8.2) were similar to previous years. The echinoderms (sea stars, sea urchins, brittle stars, sea cucumbers and sea lilies) make up the largest proportion of the biomass in the central and northern part of the Barents Sea. Most of the crustacean biomass is found in the central and eastern parts of the Barents Sea, and, as the crustaceans, the cnidarians (sea anemones, corals, hydroids) are
present with their largest biomasses in the north-eastern part of the Barents Sea. Porifera are dominating in the southwestern Barents Sea, along the western and west and northern coast of Spitsbergen/Svalbard and in the north Kara Sea.

### 2.9.2 Red King crab (Paralithodes camtschaticus)

The Ecosystem Survey shows that the distribution area for the red king crab was located between 28 and $45^{\circ} \mathrm{E}$, and therefore close to the coast (Fig 2.8.3). The westernmost catch was near the North Cape. The maximum quantity of king crab was 6 specimens per nautical mile. Compared with previous years, the total area and number of king crab catches on the Ecosystem Surveys was the same (Figure 2.8.4).

### 2.9.3 Snow crab (Chionoecetes opilio)

The Ecosystem Surveys in the Barents Sea shows an eastern distributed of the snow crab (Fig 2.8.5). This was also shown in previous years. In 2011 snow crab consists mainly ( $87 \%$ ) of young individuals with 40 mm length of carapace (Figure 2.8.6). The snowcrab was registered on 84 stations with abundances up to 2.4 thousand individuals per nautical mile and 5-25.3 $\mathrm{kg} / \mathrm{nml}$. In 2010 the snow crab was registered on 53 stations with abundances of 8-10 individuals in nearly all trawls.

### 2.9.4 Northern shrimp (Pandalus borealis)

Northern shrimp is widely distributed in the Barents Sea and was registered at $75 \%$ of the stations (Fig 2.8.7). The density ranged between 0 and $164 \mathrm{~kg} / \mathrm{nml}$. The average catch of Northern shrimp was $8 \mathrm{~kg} / \mathrm{nml}$, which is less than previous year. As in previous years, the densest concentrations were found round Spitsbergen/Svalbard and in the central parts of the Barents Sea.

### 2.10 Pollution

### 2.10.1 The sunken submarine "Komsomolets"

The potential sources for radioactive contamination from "Komsomolets" are the reactor and the nuclear torpedoes. Accurate information about the inventory of radionuclides is not publicly available. Gladkov et al. (1994) estimated, however, that the reactor core contained $2.8 \cdot 10^{15} \mathrm{~Bq}$ strontium-90 and $3.1 \cdot 10^{15} \mathrm{~Bq}$ cesium-137, which are the most important radionuclides. Further, Gladkov et al. (1994) estimated that the torpedoes contain $1.3 \cdot 10^{13} \mathrm{~Bq}$ plutonium-239.

Based on hydrographic observations, current measurements and numerical models the potential radioactive pollution has been assessed by Blindheim et al. (1994) and Heldal et al. (accepted for publication). They conclude that the submarine represent a minor radioactive pollution problem. Høibråten et al. (1997) has made the same conclusion. Despite of this fact, it is important to monitor the area around the wreck to document the radionuclide levels.

Levels of cesium-137 (Cs-137) in sediments and seawater in the vicinity of "Komsomolets" in the period 1993-2010 are shown in Figure 2.9.1. These results do not indicate a leakage of
significance from the submarine, and the levels are comparable to those found in adjacent areas. The samples collected in 2011 will be analysed in November/December 2011.

### 2.10.2 Garbage

Analyze of man-made garbage from trawl catches and surface investigations demonstrated that intensive fishery and navigation areas are the most polluted (Figure 2.9.2 and 2.9.3). Plastic dominated among pollutants in the central part of the Barents Sea. According to the distribution it is likely that this garbage is drifted into the area by the ocean currents. A large number of floating logs were observed in the central and north areas. The type of garbage observed floating at the surface is shown in Figure 2.9.4.

Plastic and wood prevailed among man-made garbage in the trawl catches (Figure 2.9.3). The occurrence of plastic in the catches increased in the northwest, northeast and east, which corresponds to the direction of the main currents. The wood might be brought to the area by ocean currents from the eastern seas because of the timber-rafting from the Siberian rivers, or it might possibly be lost from ships. This phenomenon is observed annually.

Because the bottom trawl catchability is low for small density polymer materials the amount of the anthropogenic garbage in the Barents Sea may be larger.

Dangerous and potential dangerous objects were seldom presented in the observations. In the majority of cases only inactive objects were found, which do not effect on the environment directly harmful.

Figure 2.2.12. Distribution of 0-group gonatus (Gonatus fabricii), August-October 2011.

Figure 2.3.1. Estimated density distribution of one-year-old capelin ( $\mathrm{t} /$ nautical mile ${ }^{2}$ ), August-October 2011.

Figure 2.3.2. Estimated total density distribution of capelin ( $\mathrm{t} /$ nautical mile ${ }^{2}$ ), August-October 2011.

Figure 2.3.3. Echograms of capelin in the area near King Karl's Land on 23 September 2011, from 00:11 UTC to 05.06 UTC. The collage shows how capelin descend from the upper layer when it is dark, through midwater at dawn, eventually to settle at the sea bed. Echo recordings from "Johan Hjort".

Figure 2.3.4. Echogram showing capelin (schools) and polar cod (layer), 23.09 .2011 in daylight conditions. Echo recordings from "Johan Hjort".

Figure 2.3.5. Echogram of capelin to the south-west of Franz Josef Land ( $80^{\circ} 15^{\prime} \mathrm{N}, 40^{\circ} 47^{\prime} \mathrm{E}$ ), 22.09.2011. Echo recordings from "Vilnyus".

Figure 2.3.6. Estimated density distribution of one year old polar cod ( $\mathrm{t} /$ nautical mile ${ }^{2}$ ), August-October 2011.

Figure 2.3.7. Estimated total density distribution of polar $\operatorname{cod}\left(\mathrm{t} /\right.$ nautical mile ${ }^{2}$ ), August-October 2011.

Figure 2.3.8. Echogram of polar cod to the south of Novaja Zemlja ( $70^{\circ} 42^{\prime} \mathrm{N}, 52^{\circ} 03^{\prime} \mathrm{E}$ ), 29.08.2011. Echo recordings from "Vilnyus".

Figure 2.3.9. Estimated total density distribution of herring ( $\mathrm{t} /$ nautical mile²), August-October 2011.

Figure 2.3.10. Estimated total density distribution of blue whiting ( $\mathrm{t} /$ nautical mile ${ }^{2}$ ), August-October 2011.

Figure 2.4.1. Distribution of cod (Gadus morhua morhua), August-October 2011.

Figure 2.4.2. Distribution of haddock (Melanogrammus aeglefinus), August-October 2011.

Figure 2.4.3. Distribution of saithe (Pollachius virens), August-October 2011.

Figure 2.4.4. Distribution of Greenland halibut (Reinhardtius hippoglossoides) (WCPUE, based on weight of fish), August-October 2011.

Figure 2.4.5. Distribution of golden redfish (Sebastes marinus), August-October 2011.

Figure 2.4.6. Distribution of deep-water redfish (Sebastes mentella), August-October 2011.

Figure 2.4.7. Distribution of Norway redfish (Sebastes viviparus), August-October 2011.

Figure 2.4.8. Distribution of long rough dab (Hippoglossoides platessoides), August-October 2011.

Figure 2.4.9. Distribution of Atlantic wolffish (Anarhichas lupus), August-October 2011.

Figure 2.4.10. Distribution of spotted wolffish (Anarhichas minor), August-October 2011.

Figure 2.4.11. Distribution of northern wolffish (Anarhichas denticulatus), August-October 2011.

Figure 2.4.12. Distribution of plaice (Pleuronectes platessa), August-October 2011.

Figure 2.4.13. Distribution of Norway pout (Trisopterus Esmarkii), August-October 2011.

Figure 2.4.14. Distribution of thorny skate (Amblyraja radiata), August-October 2011.

Figure 2.4.15. Distribution of northern skate (Amblyraja hyperborea), August-October 2011.

Figure 2.5.1. Area with temperature and mean catches of cod within different temperature ranges.

Figure 2.5.2. Area with temperature and mean haddock catches within different temperature ranges.

Figure 2.5.3 Mean length and hepatosomatic index of cod.

Figure 2.5.4. Mean length and hepatosomatic index of haddock.

Figure 2.5.5. Depth area depending on temperature and catches by depth in 2010.

Figure 2.5.6. Depth area depending on temperature and catches by depth in 2011.

Ecosystem cruise 2011-WP2 net

Figure 2.6.1. Zooplankton biomass during the Barents Sea Ecosystem cruise in August-September 2011. Norwegian data from vertically operated $180 \mu \mathrm{~m}$ meshed WP2 net (bottom- 0 m ).

Figure 2.7.1. Distribution of toothed whales observed in August-September 2011.

Figure 2.7.2. Distribution of baleen whales as observed in August-September 2011-

Figure 2.7.4. Distribution of alcid seabirds observed during the Norwegian part of the Joint Norwegian/Russian Ecosystem Survey 2011.

Figure 2.7.5. Distribution of pelagic birds observed during the Norwegian part of the Joint Norwegian/Russian Ecosystem Survey 2011.

Figure 2.8.1. The recorded biomass (extrapolated) of all registered bottom living evertebrate (except Nothern shrimp (Pandalus borealis) taken by Campelen bottom trawl in the Ecosystem Survey in August-October 2011

Figure 2.8.2. The relative distribution of main benthic animal groups presented as quantitative circles at each sampled station with Campelen trawl in August-October 2011.

Figure 2.8.3. Distribution of the king crab (Paralithodes camtschaticus) as recorded by Campelen bottom trawl. Standardized to numbers/1 nm, August-October 2011.

Figure 2.8.4. Catch statistics of the king crab (Paralithodes camtschaticus) recorded by the joint annual Ecosystem surveys 2005-2011.

Figure 2.8.5. The distribution of the Snow crab (Chionoecetes opilio) as recorded by the Campelen bottom trawl. Standardized to numbers/ 1 nm , on the Ecosystem Survey in August-October 2011.

Figure 2.8.6. The size composition of the Snow crab (Chionoecetes opilio) population recorded by the Ecosystem Survey in August-October 2011.

Figure 2.8.7. Distribution of northern shrimp (Pandalus borealis) as recorded by the Campelen bottom trawl on the Ecosystem Survey in August-October 2011.

Figure 2.9.1. Levels of Cs -137 in sediments (left Y -axis, blue line) and bottom water (right Y -axis, red line) in the vicinity of the sunken Russian submarine "Komsomolets". The submarine rests at a depth of about 1700 m southwest of the Bear Island.

Appendix 2. Sampling of fish in ecosystem survey 2011

| Family | Latin name/ English name | Norwegian vessels | Russian vessels | Sum |
| :---: | :---: | :---: | :---: | :---: |
| Agonidae | Leptagonus decagonus/ Atlantic poacher |  |  |  |
|  | No of stations with samples | 129 | 110 | 239 |
|  | Nos. length measured | 528 | 980 | 1508 |
|  | Nos. aged | - | 46 | 46 |
| Agonidae | Ulcina olrikii/ Arctic alligatorfish |  |  |  |
|  | No of stations with samples | - | 32 | 32 |
|  | Nos. length measured | - | 478 | 478 |
|  | Nos. aged | - | - | - |
| Ammodytidae | Ammodytes marinus/ Lesser sandeel |  |  |  |
|  | No of stations with samples | 27 | 42 | 69 |
|  | Nos. length measured | 72 | 545 | 617 |
|  | Nos. aged | - | - | - |
| Ammodytidae | Ammodytes sp./ Sandeels |  |  |  |
|  | No of stations with samples | 1 | - | 1 |
|  | Nos. length measured | 1 | - | 1 |
|  | Nos. aged | - | - | - |
| Ammodytidae | Ammodytes tobianus/ Small sandeel |  |  |  |
|  | No of stations with samples | - | 2 | 2 |
|  | Nos. length measured | - | 3 | 3 |
|  | Nos. aged | - | - | - |
| Anarhichadidae | Anarhichas sp./ Catfishes |  |  |  |
|  | No of stations with samples | 2 | 5 | 7 |
|  | Nos. length measured | 2 | 10 | 12 |
|  | Nos. aged | - | - | - |
| Anarhichadidae | Anarhichas denticulatus/ Northern wolffish |  |  |  |
|  | No of stations with samples | 42 | 7 | 49 |
|  | Nos. length measured | 62 | 8 | 70 |
|  | Nos. aged | - | - | - |
| Anarhichadidae | Anarhichas lupus/ Atlantic wolffish |  |  |  |
|  | No of stations with samples | 56 | 11 | 67 |
|  | Nos. length measured | 314 | 25 | 339 |
|  | Nos. aged | - | - | - |
| Anarhichadidae | Anarhichas minor/ Spotted wolffish |  |  |  |
|  | No of stations with samples | 44 | 15 | 59 |
|  | Nos. length measured | 98 | 36 | 134 |
|  | Nos. aged | - | - | - |
| Argentinidae | Argentina silus/ Greater argentine |  |  |  |
|  | No of stations with samples | 31 | - | 31 |
|  | Nos. length measured | 292 | - | 292 |
|  | Nos. aged | - | - | - |
| Carangidae | Trachurus trachurus/ Horse mackerel |  |  |  |
|  | No of stations with samples | 1 | - | 1 |
|  | Nos. length measured | 1 | - | 1 |
|  | Nos. aged | - | - | - |
| Chimaeridae | Chimaera monstrosa/ Rabbitfish |  |  |  |
|  | No of stations with samples | 2 | - | 2 |
|  | Nos. length measured | 2 | - | 2 |
|  | Nos. aged | - | - | - |
| Clupeidae | Clupea harengus/ Atlantic herring |  |  |  |
|  | No of stations with samples | 86 | 19 | 105 |
|  | Nos. length measured | 3628 | 221 | 3849 |
|  | Nos. aged | 72 | - | 72 |

| Family | Latin name/ English name | Norwegian vessels | Russian vessels | Sum |
| :---: | :---: | :---: | :---: | :---: |
| Clupeidae | Clupea harengus/ Kanin herring |  |  |  |
|  | No of stations with samples | - | 12 | 12 |
|  | Nos. length measured | - | 884 | 884 |
|  | Nos. aged | - | 104 | 104 |
| Cottidae | Artediellus atlanticus/ Atlantic hookear sculpin |  |  |  |
|  | No of stations with samples | 170 | 93 | 263 |
|  | Nos. length measured | 1755 | 1284 | 3039 |
|  | Nos. aged | - | - | - |
